A fitted linear regression model can be used to identify the relationship between a single predictor variable x_j and the response variable y when all the other predictor variables in the model are "held fixed". Specifically, the interpretation of β_j is the expected change in y for a one-unit change in x_j when the other covariates are held fixed—that is, the expected value of the partial ...

Steve, I like your answer and just have a nerdy footnote. In a completely randomized experiment with a binary outcome, if you want to adjust for covariates to improve precision, you can use either logit (with an average marginal effect calculation) or OLS to consistently estimate the average treatment effect, even if your model's "wrong".

53.5 million light-years away, there's a gigantic galaxy called M87 with something interesting going on inside it. Between Einstein's theory of relativity and the motion of a group of stars in the galaxy (the motion is characteristic of there being a huge gravitational mass present), scientists have believed for years that there is a supermassive black hole at the center of that galaxy.
